## II. SUBJECT INDEX

### KEY

In using this index the following should be borne in mind

- 1 Subjects, not words, have been indexed
- 2 Abstracts, not merely their titles, have been considered in indexing
- 3 The small superior numeral which accompanies each page number designates the fraction of the page in ninths in which the subject being indexed is first considered. The printed matter only, exclusive of page headings, has been thus subdivided

- 4 "P" before a page number indicates that the abstract is of a patent.

- 5 The alphabetizing of index headings has been done on the basis first of that part which comes before the comma in such headings as *Copper, metallurgy of* and *Phenol, p nitro*. E.g., these headings come before the headings *Copper compounds* and *Phenol condensation products*, respectively

- 6 Organic compounds are indexed on the basis of "parent compounds," or more accurately, "index compounds" (see Introduction), the names of substituent radicals following in alphabetical order. The system of naming organic compounds which has been used is outlined in the Introduction below. Esters and salts of organic acids are, in general, indexed under the names of the acids. Notes in the index under the appropriate headings explain the few exceptions.

- 7 An asterisk (\*) following the name of an organic compound entered in the index signifies that the name, or numbering, or both are the author's own and may not conform to the system of nomenclature used in this index. This sign is used where it has seemed inadvisable, owing to incomplete information, to attempt to make the name conform to the system, or where the author's name, differing widely from the one given to the compound by the indexer, is given as an extra entry.

- 8 A dagger (†), which follows the names of a few compounds, signifies that the entry is an extra one, the name being only slightly less favored than the one chosen for the other entry. The preferred name can be determined by reference to the Formula Index.

*The desirability of making the index readily usable without the need of reference to an elaborate introduction has been held constantly in mind. Although an introduction seems desirable and should be helpful nevertheless the index is dependent neither on the key nor on the Introduction. Numerous cross references are given throughout the index and notes appear in connection with certain headings. An examination of the Introduction which follows, should be especially helpful to those interested in looking up organic compounds.*

## INTRODUCTION

**General policy.** The indexing of subjects, as opposed to word indexing, has been emphasized. This avoids omissions, scattering and unnecessary entries, with the abundant cross references used it means that one should be able to find all of the references on any subject with certainty and with a minimum of effort. The words used as subject headings or in modifying phrases are not necessarily to be found in the abstracts but an expression of the idea suggested will be found within or beginning in the ninth of the page designated by the small superior numeral following the page number. Chemical compounds have been named and entered systematically, the system used is outlined below. All new compounds and all elements, compounds and other substances for which new data are given have been indexed, with the single exception of new compounds for which no names or structures have been given. Such compounds are entered only in the Formula Index. The Subject Index is in no other respect altered because of the Formula Index.

**Modifying phrases.** In writing such phrases for the entries under any heading the words have been arranged so that the idea considered to be the most important is expressed at the beginning whenever feasible and this procedure, as well as the selection of the words for this purpose, has been governed by numerous formulated general principles and specific rules. *E.g.*, "detection of" has been used consistently whenever correct at the beginning of the modifications in indexing subjects treated from a qualitative analytical point of view, instead of permitting a scattering under such additional phrases as "test for," "reaction for," etc., regardless of what words may have been used in the text. In the case of appropriate headings the selection of first words for modifications has been made on the basis of a definite system of classification. Under a few large headings two or more entries have been made on indexing a subject in a single abstract in case two or more ideas could be used equally well to start the modifying phrase. In alphabetizing modifying phrases prepositions at the beginning have been ignored.

**References to fractions of the page.** One can readily estimate ninths of a page with considerable accuracy by placing the fore or middle finger one-third of the distance from the top of the printed matter on the page and the thumb one-third of the distance from the bottom—a procedure very easily carried out.

**Inorganic compounds.** Simple inorganic compounds are entered under the usual names. In indexing compounds of iron, gold, copper and tin such headings as *Iron sulfates*, under which the "ous" and "ic" salts are entered, have been used rather than headings beginning with "ferric(ous)," "auric(ous)," "cupric(ous)" or "stannic(ous)." Acid salts, such as  $\text{NaH}_2\text{PO}_4$ , are entered under such headings as *Sodium phosphates*. With the exception of a few common compounds such as carbon dioxide and carbon monoxide, compounds of a given element with another or with a definite radical, which differ only in valence relations, are grouped. *E.g.* the various oxides of nitrogen are grouped under the heading *Nitrogen oxides* and classified there. Complex inorganic compounds which cannot be given definite names satisfactory for indexing are usually indexed under the heading which represents the class of compounds concerned and under a heading beginning with the name of the significant element. *E.g.*, dichlorotetraamminecobaltic chloride would be indexed under *Ammino compounds* and under *Cobalt compounds*. The Formula Index, which follows the Subject Index, should be particularly helpful in locating complex compounds.

**Organic compounds.** The system used for naming and indexing organic compounds is the same as that in use starting with the 1916 volume. An explanation of it by Austin M. Patterson and Carleton B. Curran, who are its originators, has appeared in another

journal of the Society.<sup>1</sup> The system is based on existing usage and follows this as far as is practicable, so that a great many familiar names are unaffected. Only the general principles will be given here, but in the index itself will be found abundant cross references and also notes under *Alcohols*, *Ketones*, etc., indicating how compounds of these classes are named.<sup>2</sup>

1 The 'chief function' of a compound is expressed in the main part of the name wherever possible and not as a substituent thus Pyrrolecarboxylic acid not carboxy pyrrole, ethyl alcohol or ethanol, not hydroxyethane pentanone not ketopentane

2 In compounds of mixed function the chief function is determined from the following order of precedence<sup>3</sup> 'onium' compounds, acid (carboxylic first) acid halide, amide imide aldehyde, nitrile ketone, alcohol phenol mercaptan amine imine ether sulfide (and sulfoxide and sulfone) Thus hydroxybenzonitrile not cyanophenol aminophenol, not hydroxyaniline

3 A multiple chief function is expressed where feasible as diol dicarboxylic acid etc. rather than as hydroxy—ol, carboxy—acid etc. But amino and imino groups attached to cyclic bases are treated as substituents as aminopyridine

4 The index compound should be as large and the substituents as small as is practicable in conformity with the above rules as ethylbenzene not phenylethane. But such names as diphenylethane and triphenylcarbinol are exceptions. When the chief function is in a side chain attached to a complex nucleus, 'additive' names are preferred in order to harmonize 1 and 4, thus, naphthaleneacetic acid, not naphthyl acetic acid (with the result that the compound is indexed with other naphthalene derivatives instead of under acetic acid, see 5)

5 The main part of the name with its functional ending if any, is placed first in the index, the names of substituents following thus chloroacetic acid would appear in the index as *Acetic acid*, *chloro-* and dihydroxyanthraquinone as *Anthraquinone dihydroxy-*. The part thus placed first is called the 'index compound,' it may or may not be the "parent compound" (in the second example the parent compound is anthracene)

6. Names in which two functions are expressed in the index compound, as propanolone, cyclopentanonecarboxylic acid, are avoided, except that a few very common ones, such as phenolsulfonic acid are used (indicated by cross references)

7 The names of the substituent radicals in the name of a compound are arranged in alphabetical order, as, benzylethylmethylphenylammonium chloride. The number of radicals of each kind does not affect the order (e. g., *benzyl* precedes *ethyl* no matter how many of each are present), but the compound name of a substituted radical is treated as a unit with its own alphabetic position, thus *dimethylamino*,  $\text{Me}_2\text{N}$ , follows *benzyl* but precedes *ethyl*. When the complete name has been formed it is alphabetized as any other word

8 Parentheses, brackets and even braces are used where necessary to mark off complex radical names

9 Familiar methods of numbering are employed (Greek letters for acids, alcohols etc., and for side chains, arabic numerals for Geneva names and rings). The numbering of complex nuclei is shown in the index under the parent compounds, it is practically identical with that of Richter's 'Lexikon' so far as that work goes. For the more

<sup>1</sup> Patterson and Curran *J. Am. Chem. Soc.* **39** 1623-34 (1917)

<sup>2</sup> For the principles used in naming certain parent ring systems and especially in distinguishing isomeric forms by the use of bracketed numbers and letters in the middle of the name see Patterson *J. Am. Chem. Soc.* **40**, 3074-87 (1918)

<sup>3</sup> This order is an attempt to express not the relative chemical importance of functions but general usage in selecting one of them for the ending of the name. For a recent study of the literature on this question see Patterson *Rec. trav. chim.*, **48**, 1012-17 (1929)

recently discovered forms the 'Proposed International Rules for Numbering Organic Ring Systems'<sup>1</sup> have been adopted as a standard.

10 When two or more numberings are equally indicated that one is chosen which gives the smallest number or numbers for the *chief function*, then for *double bonds* if these must be regarded, then for *triple bonds*, then for *points of attachment* (doubled molecules), then for *substituents*.

11 Unnecessary numbers are avoided thus, in  $\Delta^1$ -1-cyclohexanol the 1 is not needed because by the rules in paragraph 10 the OH group is assumed to be in position 1

12 Numbers in parentheses are used to indicate the position of entering hydrogen necessary to the existence of the compound, thus, 4(3)-quinolone is equivalent to 3,4-dihydro-4-oxoquinoline.

13 Doubled molecules or radicals are indicated by names commencing with *bi* (as *o,o* biphenol, biphenyl,  $\Delta''$  bipiperidine). *Bi* is used for like molecules united by a bivalent radical and for double complex expressions, as, methylenebisphenol bis(dimethylamino)-
